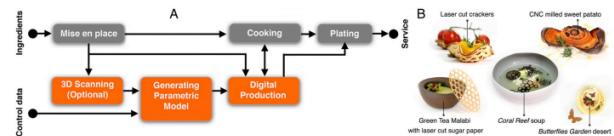

Figure 1: (A) A general scheme of a hybrid cooking procedure, using manual and digital techniques to allow personalization of a dish. Gray: traditional cooking. Orange: interaction with digital procedure. (B) Five examples of dishes made using hybrid cooking techniques.

### ABSTRACT

Several recent projects have introduced digital machines to the kitchen, yet their impact on culinary culture is limited. We envision a culture of Digital Gastronomy that enhances traditional cooking with new HCI capabilities, rather than replacing the chef with an autonomous machine. Thus, we deploy existing digital fabrication instruments in traditional kitchen and integrate them into cooking via *hybrid recipes*. This concept merges manual and digital procedures, and imports parametric design tools into cooking, allowing the chef to personalize the tastes, flavors, structures and aesthetics of dishes. In this paper we present our hybrid kitchen and the new cooking methodology, illustrated by detailed recipes with degrees of freedom that can be set digitally prior to cooking. Lastly, we discuss future work and conclude with thoughts on the future of hybrid gastronomy.

### INTRODUCTION

Recently we have witnessed a growing number of projects importing digital technologies into the kitchen, in the form of food printers [18], robotic cooks [6,34,43], or theoretical research on the semantics and procedural relationship in culinary recipes [2,17,27,37]. Nevertheless, although the vision of Digital Gastronomy is not new [46], the potential of computers to enhance our culinary and cooking culture is still awaiting its bloom. Many of the new digital cooking developments present a high degree of technical sophistication, and are often biased towards quantitative reductionism of culinary culture. These projects suggest that cooking can be represented by a finite set of instructions, which can then be analytically manipulated to control fully autonomous machines.

The kitchen is more than a territory for digital augmentation seeking efficiency and control: it is a place where culture and tradition co-exist [1], and creativity is celebrated [15]. Yet, although it holds major potential for interaction studies, within the HCI community the discourse on cooking is still limited, as recent research papers largely discuss eating habits, diet and the food media [5,12,43].

Figure 1: Joinery's parametric joint profiles for laser cutting.

**ABSTRACT**  
 Laser cutting is widely used by industrial designers and mechanical engineers as a rapid modeling tool. However, designing and fabricating laser cut assemblies can be a complex and tedious process, especially for novice designers. Through our research, we developed *Joinery*, a parametric joint generation tool for laser cut assemblies. Through *Joinery*, designers simply define connections between parts of an assembly, while the system generates the joints. *Joinery* supports fabrication-aware design through six different joint profiles that cater to different material and design needs. In this paper, we illustrate the use of *Joinery* as a creativity support tool in an industrial design process, and present several artifacts resulting from the tool. In addition, we discuss our findings from deploying this system in a college-level industrial design class.

**INTRODUCTION**  
 Digital fabrication has been celebrated in recent years as a catalyst for shifting our design and manufacturing away from mass production, and into a "maker of" paradigm where we can make "almost everything" [5]. Its impact has been increasingly discussed within the HCI (human-computer interaction) academic field, and many innovative digital fabrication tools have been proposed to facilitate creative "making" endeavors [2,8,17,20]. Certainly, mechanical engineers and industrial designers benefit greatly from the advance of digital fabrication tools and processes—3D printers and laser cutters are employed as rapid modeling

## Platener: Low-Fidelity Fabrication of 3D Objects by Substituting 3D Print with Laser-Cut Plates

Dustin Beyer, Serafima Gurevich, Stefanie Mueller, Hsiang-Ting Chen, Patrick Baudisch  
Hasso Plattner Institute, Potsdam, Germany  
[{firstname.lastname}@hpi.uni-potsdam.de](mailto:{firstname.lastname}@hpi.uni-potsdam.de)

### ABSTRACT

This paper presents Platener, a system that allows quickly fabricating intermediate design iterations of 3D models, a process also known as low-fidelity fabrication. Platener achieves its speed-up by extracting straight and curved plates from the 3D model and substituting them with laser cut parts of the same size and thickness. Only the regions that are of relevance to the current design iteration are executed as full-detail 3D prints. Platener connects the parts it has created by automatically inserting joints. To help fast assembly it engraves instructions. Platener allows users to customize substitution results by (1) specifying fidelity-speed tradeoffs, (2) choosing whether or not to convert curved surfaces to plates bent using heat, and (3) specifying the conversion of individual plates and joints interactively.

Platener is designed to best preserve the fidelity of *functional* objects, such as casings and mechanical tools, all of which contain a large percentage of straight/rectilinear elements. Compared to other low-fab systems, such as faBrickator and WirePrint, Platener better preserves the stability and functionality of such objects: the resulting assemblies have fewer parts and the parts have the same size and thickness as in the 3D model.

To validate our system, we converted 2,250 3D models downloaded from a 3D model site (*Thingiverse*). Platener achieves a speed-up of 10x or more for 39.9% of all objects.

Figure 1. A selection of objects created using Kyub, a software system that allows users to design 3D objects for laser cutting. By affording shod box structures, objects made using Kyub are very strong. This allows users to make tables, shelves and chairs that can hold a person. (All shown objects are assembled from thin plywood sheets—pressure fit, not glued).

**ABSTRACT**  
We present an interactive editing system for laser cutting called Kyub. Kyub allows users to create models efficiently in 3D, which it then unfolds into the 2D plates laser cutters expect. Unlike earlier systems, such as FlatFab, kyub affords construction based on closed box structures, which allows users to turn very thin material, such as 4mm plywood, into objects capable of withstanding large forces, such as chair users can actually sit on. To afford these structures, even a small object found with a simple finger-joint “bowel”—a structure we found to be capable of withstanding over 500kg of load. Users then extend their model by attaching additional boxes; boxes merge automatically, resulting in larger, yet equally strong structures. While the strength of stacking boxes allows kyub to offer the strength of affordance and ease of use of a voxel-based editor, boxes are not confined to a grid and readily combine with kyub’s various geometry deformation tools. In our technical evaluation, objects built with kyub had hundreds of kilograms of loads. In our user study, non-engineers rated the learnability of kyub 6.1/7.

## Interactive Construction: Interactive Fabrication of Functional Mechanical Devices

Stefanie Mueller, Pedro Lopes, and Patrick Baudisch  
Hasso Plattner Institute, Potsdam, Germany  
(stefanie.mueller, pedro.lopes, patrick.baudisch)@hpi.uni-potsdam.de

### ABSTRACT

Personal fabrication tools, such as laser cutters and 3D printers allow users to create precise objects quickly. However, working through a CAD system removes users from the workpiece. Recent interactive fabrication tools reintroduce this directness, but at the expense of precision.

In this paper, we introduce *constructable*, an interactive drafting table that produces precise physical output in every step. Users interact by drafting directly on the workpiece using a hand-held laser pointer. The system tracks the pointer, beautifies its path, and implements its effect by cutting the workpiece using a fast high-powered laser cutter.

*Constructable* achieves precision through tool-specific constraints, user-defined sketch lines, and by using the laser cutter itself for all visual feedback, rather than using a screen or projection. We demonstrate how *Constructable* allows creating simple but functional devices, including a simple gearbox, that cannot be created with traditional interactive fabrication tools.

**Author Keywords:** interactive fabrication; laser cutting; rapid prototyping; sketching; construction; mechanics.

### INTRODUCTION

Rapid prototyping/personal fabrication tools, such as 3D printers and computer controlled milling machines help users create one-off prototypes rapidly.

The process places CAD software at the front-end to per-

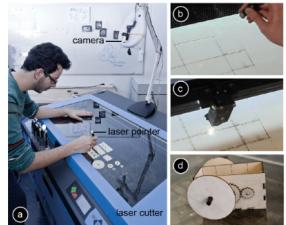

Figure 1: (a) *Constructable* users interact by drafting directly on the workpiece with hand-held lasers. (b) Here the user sketches a finger joint across two objects (c) The system responds by cutting the desired joint using the cutting laser. (d) *Constructable* allows creating precise & functional mechanical objects, such as this simple motorized vehicle.

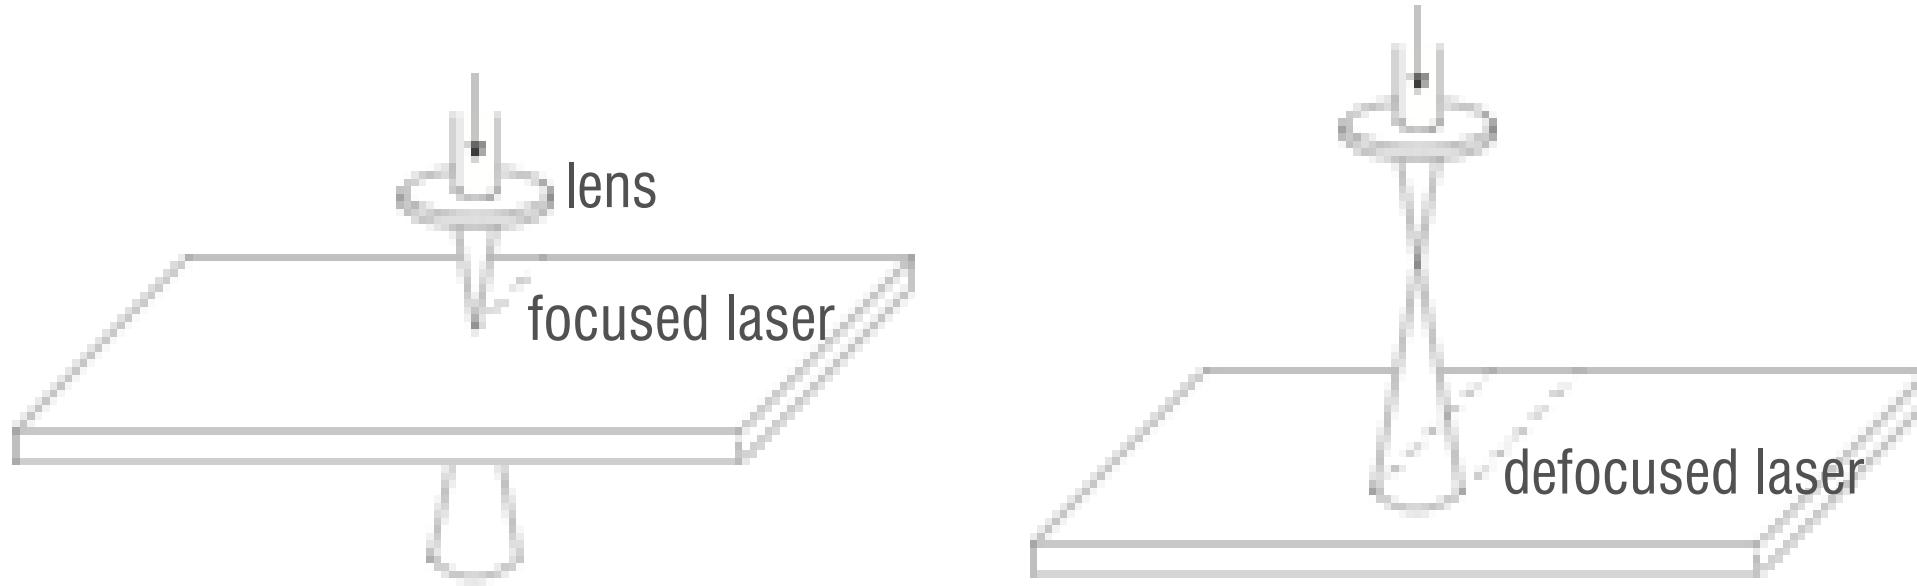

(3) *Precision*: constructions aids, such as constraints allow users to precisely manufacture pieces that can perform mechanical functions.

On the flipside, the transition from traditional tools to personal fabrication tools means that all editing is now done on a computer screen, which removes users from the workpiece and prevents users from refining their design interactively along the way [7,11].

## LaserOrigami: Laser-Cutting 3D Objects

Stefanie Mueller, Bastian Kruck, and Patrick Baudisch

Hasso Plattner Institute, Potsdam, Germany

{stefanie.mueller, bastian.kruck, patrick.baudisch}@hpi.uni-potsdam.de

### ABSTRACT

We present LaserOrigami, a rapid prototyping system that produces 3D objects using a laser cutter. LaserOrigami is substantially faster than traditional 3D fabrication techniques such as 3D printing and unlike traditional laser cutting it results in 3D objects without manual assembly. The key idea behind LaserOrigami is that it achieves three-dimensionality by folding and stretching the workpiece, rather than by placing joints, thereby eliminating the need for manual assembly. LaserOrigami achieves this by heating up selected regions of the workpiece until they become compliant and bend down under the force of gravity. LaserOrigami administers the heat by defocusing the laser, which distributes the laser's power across a larger surface. LaserOrigami implements cutting and bending in a single integrated process by automatically moving the cutting table and the defocused laser to the workpiece; it is already fully assembled. We present the three main design elements of LaserOrigami: the bend, the suspender, and the stretch, and demonstrate how to use them to fabricate a range of physical objects. Finally, we demonstrate an *interactive fabrication* version of LaserOrigami, a process in which user interaction and fabrication alternate step-by-step.

## Auto-stacking

LaserStacker creates 3D objects using a new cut/weld/heal process.

## LaserStacker: Fabricating 3D Objects by Laser Cutting and Welding

Udayan Umapathi, Hsiang-Ting Chen, Stefanie Mueller, Ludwig Wall,  
Anna Seufert, Patrick Baudisch  
Hasso Plattner Institute, Potsdam, Germany  
{firstname.lastname}@hpi.de

**ABSTRACT**  
Laser cutters are useful for rapid prototyping because they are fast. However, they only produce planar 2D geometry. One approach to creating non-planar objects is to cut the object in horizontal slices and to stack and glue them. This approach, however, requires manual effort for the assembly and time for the glue to set, defeating the purpose of using a fast fabrication tool.

We propose eliminating the assembly step with our system *LaserStacker*. The key idea is to use the laser cutter to not only cut but also to *weld*. Users place not one acrylic sheet, but a stack of acrylic sheets into their cutter. In a single process, *LaserStacker* cuts each individual layer to shape (through all layers above it), *welds* layers by melting material at their interface, and *heals* undesired cuts in higher layers. When users take out the object from the laser cutter, it is already assembled.

To allow users to model stacked objects efficiently, we built an extension to a commercial 3D editor (*SketchUp*) that provides tools for defining which parts should be connected and which remain loose. When users hit the *export* button, *LaserStacker* converts the 3D model into cutting, welding, and healing instructions for the laser cutter.

We show how *LaserStacker* not only allow making static objects, such as architectural models, but also objects with moving parts and simple mechanisms, such as scissors, a simple pinball machine, and a mechanical toy with gears.

### ABSTRACT

This study proposes BlowFab, a prototyping method used to create a 2.5-dimensional prototype in a short time by combining laser cutting and air-inflating techniques. The user creates adhesive areas and inflatable areas by engraving and cutting multilayered plastic sheets using a laser cutter. These adhesive areas are fused automatically by overlapping two crafted sheets and softening them with a heater. The user can then create hard prototypes by injecting air into the sheets.

Objects can be bent in any direction by cutting incisions or engraving a resistant resin. The user can create uneven textures by engraving a pattern with a heat-resistant film. These techniques can be used for prototyping various strong inflatable objects. The finished prototype is strong and can be collapsed readily for storage when not required.

In this study, the design process is described using the proposed method. The study also evaluates possible bending mechanisms and texture expression methods along with various usage scenarios and discusses the resolution, strength, and reusability of the prototype developed.

**INTRODUCTION**  
Inflatable structures such as temporary buildings and portable kayaks are widely used owing to their light weight and portability. These structures derive their strength from the internal pressure of air against their membranes. In the recent past, several studies of soft robotics and shape changing interfaces of human-computer interaction (HCI) have proposed techniques for creating inflatable

three-dimensional (3D) objects using soft materials such as silicone rubber [21, 13]. These techniques can be used to create programmable shapes, such as soft actuators and temporary houses by pumping air into fibers. Large objects such as temporary houses are flattened or made compact after use. Because these products are made of soft elastic materials such as rubber, it is necessary to continue to pump air into the products to maintain their shape. In addition, there is a risk of air escaping from even a small hole, making the structure unusable. Detecting these tiny holes can be challenging. This risk also reduces their potential usage in even slightly tough environments and terrains.

Blow molding, which is a manufacturing method used to make plastic bottles, can be used to produce a hard product by injecting air into a thermo-reversible resin capsule. This method is flexible and the shape of the object can be changed freely when the material is heated and softened. However, a mold is necessary when making an object using blow molding.

Therefore, we propose BlowFab, which combines the blow molding technology using a thermo-reversible resin, the technology used for making inflatable products, and rapid digital fabrication technology to create hard inflatable products. BlowFab can be used to create a 3D prototype in a short time by combining engraving and air-inflating techniques. The user begins by creating adhesive and inflatable areas by engraving and cutting multilayered plastic sheets using a laser cutter. Two such cutout sheets are softened using a heater (or a heat gun) and placed together. The adhesive areas are fused automatically, leaving the space for inflation. The user can create hard prototypes by injecting air into the sheets. The objects can be bent in any direction by making a specially designed cutting pattern or engraving a resistant resin. The user can even create uneven textures by engraving a pattern with a heat-resistant film. These techniques can be used for prototyping various strong inflatable and reusable objects (Figure 1).

### ABSTRACT

Prototyping compact devices with unique form factors often requires the PCB manufacturing process to be outsourced, which can be expensive and time-consuming. In this paper, we present Fibercuit, a set of rapid prototyping techniques to fabricate high-resolution, flexible circuits on-demand using a fiber laser engraver. We showcase techniques that can laser cut copper-based composites to form fine-pitch conductive traces, laser fold copper substrates that can form kirigami structures, and laser solder surface-mount electronic components onto off-the-shelf solder paste pastes. Combined with our software pipeline, end-to-end design and fabricate flexible circuits which are dual-layer and three-dimensional, thereby exhibiting a wide range of form factors. We demonstrate Fibercuit by showcasing a set of examples, including a custom dice, flex cables, custom end-stop switches, electromagnetic coils, LED earrings and a circuit in the form of kirigami crane.

### 1 INTRODUCTION

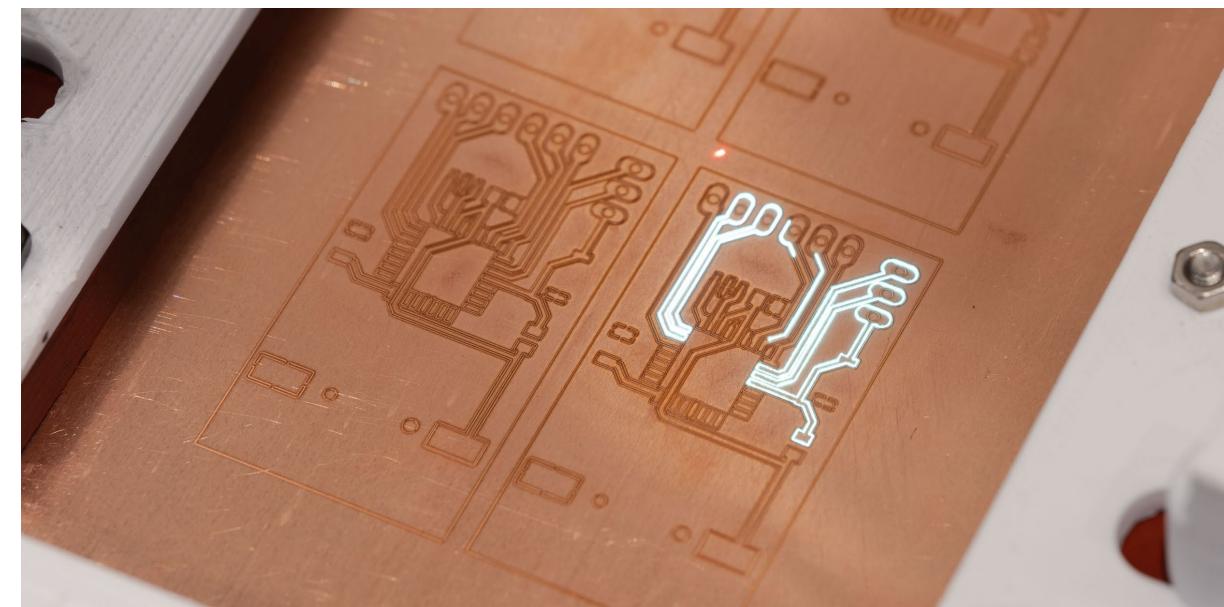

In the ongoing effort to weave computing into our daily lives [49], designing smart devices has been a major research focus in HCI. As these devices aim to discreetly recede into the environment or onto the user's body, they usually possess small and unconventional form factors. Building and prototyping such devices requires multiple rounds of iterative design to successfully integrate the function into the form. While the consumerization of 3D printers and laser cutters has shortened the iteration cycle, this advancement has been largely withheld from the PCB design and manufacturing process. Due to their flexibility and convenience, breadboards are still the most popular method to quickly prototype circuits. Apart from requiring bulky breakout boards for all surface-mounted components (SMD),

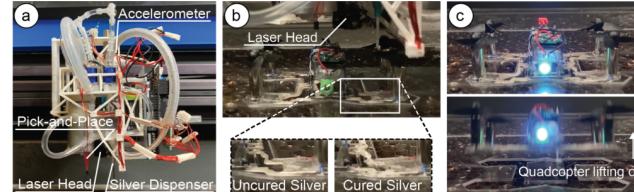

Figure 1: LaserFactory is an integrated fabrication process that creates fully functional devices. (a) Our hardware add-on to an existing laser cutter consists of a silver dispenser and pick-and-place mechanism and allows the machine to not only cut geometry, but also create circuit traces and assemble electronic components. Our accelerometer-based motion classifier enables the add-on to interface with the laser cutter without the need to change the underlying firmware. (b) To cure the deposited silver traces, we developed a laser soldering method that uses the heat of the defocused laser to make the traces conductive. (c) After laser soldering, the fabricated device is fully functional.

### ABSTRACT

LaserFactory is an integrated fabrication process that augments a commercially available fabrication machine to support the manufacture of fully functioning devices without human intervention. In addition to creating 2D and 3D mechanical structures, LaserFactory creates conductive circuit traces with arbitrary geometries, picks-and-places electronic and electromechanical components, and solders them in place. To enable this functionality, we make four contributions. First, we build a hardware add-on to the laser cutter head that can deposit silver circuit traces and assemble components. Second, we develop a new method to cure dispensed silver using a CO<sub>2</sub> laser. Third, we build a motion-based signaling method

that allows our system to be readily integrated with commercial laser cutters. Finally, we provide a design and visualization tool for making functional devices with LaserFactory. Having described the LaserFactory system, we demonstrate how it is used to fabricate devices such as a fully functioning quadcopter and a sensor-equipped wristband. Our evaluation shows that LaserFactory can assemble a variety of differently sized components (up to 65g), that these can be connected by narrow traces (down to 0.75mm), and that our acceleration-based sensing scheme works reliably (to 99.5% accuracy).
