ABSTRACT

Previous work has demonstrated the viability of applying offline analysis to interpret forearm electromyography (EMG) and classify finger gestures on a physical surface. We extend those results to bring us closer to using muscle-computer interfaces for always-available input in real-world applications. We leverage existing taxonomies of natural human grips to develop a gesture set covering interaction in free space even when hands are busy with other objects. We present a system that classifies four-finger gestures online and we introduce a bi-manual paradigm that enables use in interactive systems. We report experimental results demonstrating four-finger classification accuracies averaging 79% for pinching, 85% while holding a travel mug, and 88% when carrying a weighted bag. We further show generalizability across different arm postures and explore the trade-offs of providing real-time visual feedback.

ACM Classification: H.1.2 [User/Machine Systems]; H.5.2 [User Interfaces]: Input devices and strategies; B.4.2 [Input/Output Devices]: Channels and controllers

General terms: Design, Human Factors
Keywords: Electromyography (EMG), Muscle-Computer Interface, input, interaction.

INTRODUCTION
Our hands and our ability to control them have evolved over thousands of years, yielding an amazing ability to precisely manipulate tools. As such, we have often crafted our environments and technologies to take advantage of this ability. For example, many current computer interfaces require manipulating physical devices such as keyboards, mice, and joysticks. Even future looking research systems

Previous work has explored hands-free and implement-free input techniques based on a variety of sensing modalities. For example, computer vision enables machines to recognize faces, track movement and gestures, and reconstruct 3D scenes [24]. Similarly, speech recognition allows for hands-free interaction, enabling a variety of speech-based desktop and mobile applications [8, 11]. However, these technologies have several inherent limitations. First, they require observable interactions that can be inconvenient or socially awkward. Second, they are relatively sensitive to environmental factors such as light and noise. Third, in the case of computer vision, sensors that visually sense the environment are often susceptible to occlusion.

We assert that computer input systems can leverage the full bandwidth of finger and hand gestures without requiring the user to manipulate a physical transducer. In this paper, we show how forearm electromyography (EMG) can be used to detect and decode human muscular movement in real time, thus enabling interactive finger gesture interaction. We envision that such sensing can eventually be achieved with an unobtrusive wireless forearm EMG band (see Figure 1).

Previous work exploring muscle-sensing for input has primarily focused either on using a single large muscle (rather than the fingers) [2, 3, 4, 22, 25], which does not provide the breadth of input signals required for computer input, or on using multiple muscles and sensors placed directly to a surface [3, 4, 15, 21, 23, 25], which is not a realistic usage scenario for always-available input devices. Saponas et al. [18] demonstrated the feasibility of using offline machine learning techniques to interpret forearm muscle-sensing and classify finger gestures on a surface. We extend their offline classification results to achieve online classification.

ABSTRACT

We propose and study a new input modality, WristWhirl, that uses the wrist as an always-available joystick to perform one-handed continuous input on smartwatches. We explore the influence of the wrist's bio-mechanical properties for performing continuous input while standing still and walking, while standing still and walking. Through a user study, we examine the impact of performing 8 distinct gestures (4 directional marks, and 4 free-form shapes) on the stability of the watch surface. Participants were able to perform directional marks on the watch surface at an average rate of half a second and free-form shapes at an average rate of approximately 1.5secs. The free-form shapes could be recognized by a S1 gesture recognizer with an accuracy of 93.8% and by three human inspectors with an accuracy of 85%. From these results, we designed and implemented a proof-of-concept device by augmenting the watchband using an array of proximity sensors, which can be used to draw gestures with high quality. Finally, we demonstrate a number of scenarios that benefit from one-handed continuous input on smartwatches using WristWhirl.

INTRODUCTION
Interaction with a smartwatch often necessitates both hands, especially for continuous input such as flicking the device screen with the opposite-side hand (OSH) [34]. This becomes tedious as such wearable devices are predominantly valuable for glancing at information when the users' hands are occupied while holding objects or busy at other tasks.

Efforts are underway at developing methods to allow same-side hand (SSH) operation on smartwatches. However, these

have primarily targeted discrete input operations, such as in the case of micro-interactions [21, 33] or for assigning commands to finger postures [10, 24, 36]. Tilting the wrist is a viable approach [9], but comes at the cost of quickly losing visual contact with the display as tilt movements can exceed the acceptable range of motion boundaries [9, 23]. Performing more expressive continuous gestures still remains challenging using the same-side hand.

We study and present an alternative approach, WristWhirl,

an interaction technique that uses continuous wrist movements, or whirls, for one-handed operation on smartwatches (Figure 1). When observing the collective range-of-motions of the wrist along each of its axes of movement [12] (see Figure 2 and the WRIST AS JOYSTICK section), it is clear that the wrist is a natural input device. We explore the ability of the human wrist to perform complex gestures using full wrist motions, or wrist whirls. We first demonstrate that wrist whirl is sufficiently expressive to capture common touch interactions as well as generate free-form shapes (Figure 3). We then demonstrate screen viewing stability. To validate the use of WristWhirl in different application scenarios, we implemented a proof-of-concept wristband sensor (Figure 1 left) by augmenting the strap of a smartwatch using an array of infrared proximity sensors, facing the user's palm. The sensors detect the wrist's position and orientation, sending the degree of flexion/extension and ulnar/radial deviation of the wrist motion. Our preliminary system evaluation showed that the user could use the prototype to draw gestures at a quality comparable to that achieved by a commercial motion tracking system (e.g. Vicon [3]). Our approach does not seek to replace two-handed use of smartwatches, but instead provides an alternative to same-sided smartwatch input.

DESCRIPTION

DOCUMENTS

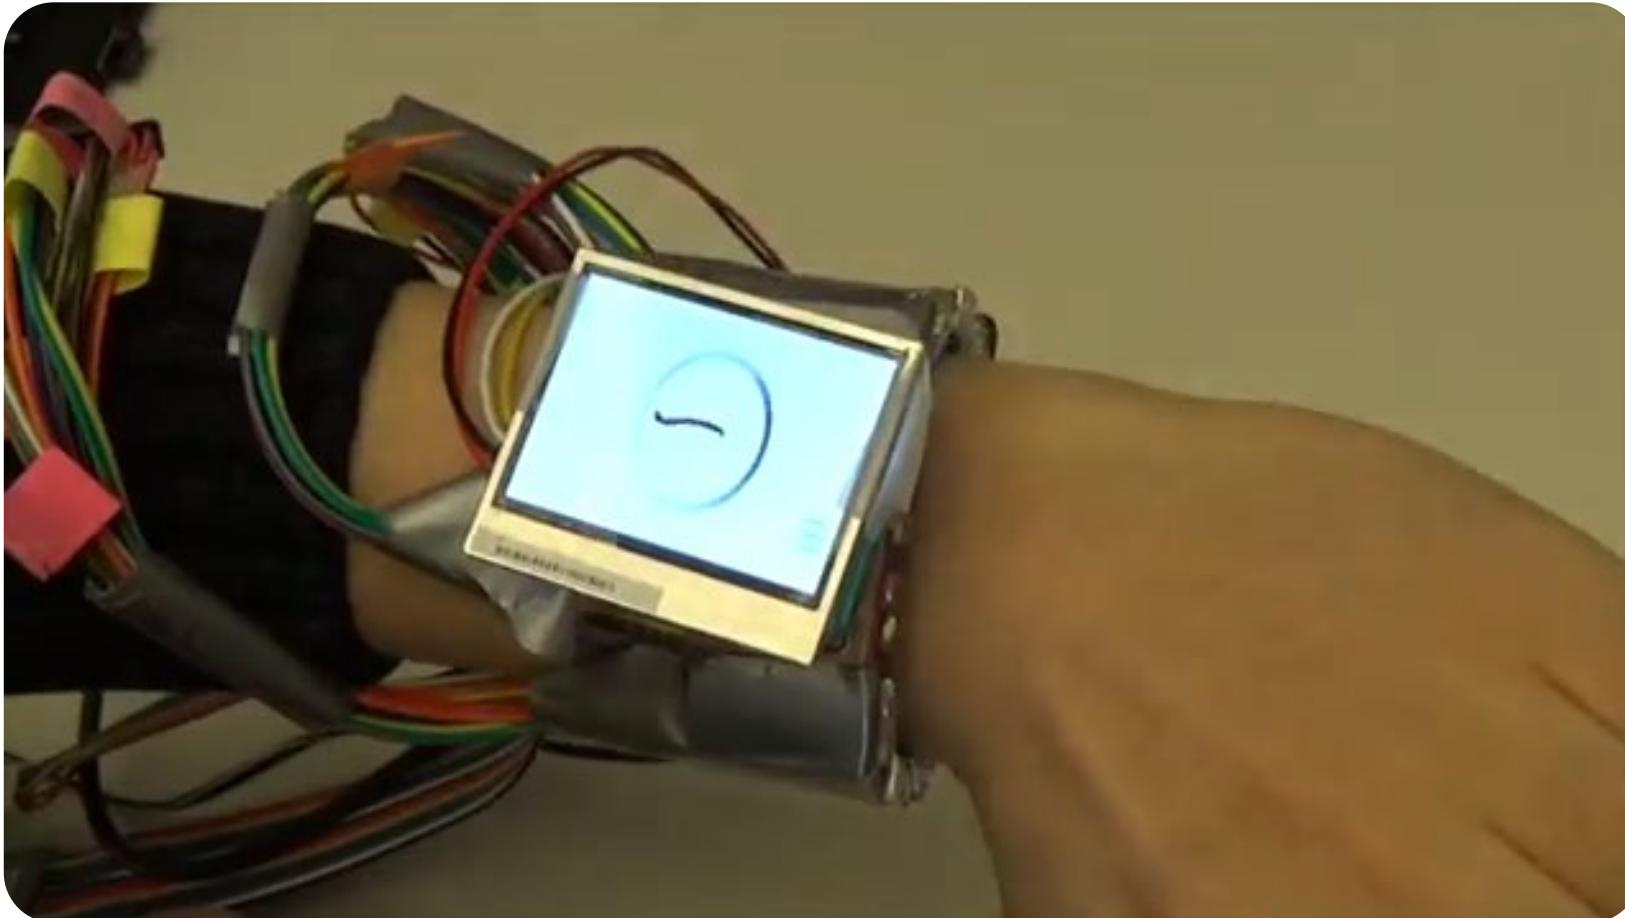

The Minisense 100 from Measurement Specialties is a low-cost cantilever-type vibration sensor loaded by a mass to offer high sensitivity at low frequencies. Useful for detecting vibration and 'tap' inputs from a user. A small AC and large voltage (up to +/-90V) is created when the film moves back and forth. A simple resistor should get the voltage down to ADC levels. Can also be used for impact sensing or a flexible switch.

Comes with machine pins that allows for horizontal mounting.

ABSTRACT

SkinTrack is a wearable system that enables continuous touch tracking on the skin. It consists of a ring, which emits a continuous high frequency AC signal, and a sensing wristband with multiple electrodes. Due to the phase delay inherent in a high-frequency AC signal propagating through the body, there are differences in phase between pairs of electrodes. SkinTrack measures these phase differences to compute a 2D finger touch location. Our approach segments touches into two categories: accurate, and vague 2D location of touches with a mean error of 7.6mm. As our approach is compact, non-invasive, low-cost and low-powered, we envision the technology being integrated into future smartwatches, supporting rich touch interactions beyond the confines of the small touchscreens.

INTRODUCTION
Small wearable devices—such as smartwatches and digital jewelry—are fast becoming viable computing platforms. However, their small size severely limits the user experience. For example, touchscreens on smartwatches suffer not only from a paucity of interactive surface area, but also must contend with significant finger occlusion. In response, the interfaces on these devices rely on basic input modalities (often four or fewer onscreen buttons, or even just directional swipes). In response, many research efforts have investigated how to leverage the area around devices to

INTRODUCTION
Watches and wearables are unique in that they reside on the body, presenting great potential for always-available input and interaction. Their position on the wrist makes them ideal for capturing *bio-acoustic* signals. We developed a custom smartwatch kernel that boosts the sampling rate of a smartwatch's built-in accelerometer to 4000 Hz. With this new source of high-fidelity data, we uncover a wide range of applications. For example, we can use bio-acoustic data to classify hand gestures such as flicks, claps, scratches, and taps, which combine with on-device motion tracking to create a wide range of expressive input modalities. Bio-acoustic signals also capture the vibrations of growing mechanical or motor-powered objects, enabling passive object recognition that can augment everyday experiences with context-aware functionality. Finally, we can generate step count data using a watch's built-in shaker sensor that data can be transmitted through the human body. Overall, our contributions unlock user interface techniques that previously relied on special-purpose and/or cumbersome instrumentation, making such interactions considerably more feasible for inclusion in future consumer devices.

Figure 1. Actuated face movements and usage scenarios: (a) face orbiting for view adaption; (b) face translating outside sleeve; (c) face rotating to indicate an important call; (d) face tilting for sharing; (e) face rising for force feedback.

ABSTRACT

We propose and explore actuating a smartwatch face to enable extended interactions. Five face movements are defined: rotation, hingeing, translation, rising, and orbiting. These movements are incorporated into interaction techniques to address limitations of a fixed watch face. A 20-person study used concept videos of a passive low-fidelity prototype to confirm the feasibility of these movement types.

A second 20-person study uses 3D rendered animations to assess social acceptability and perceived comfort for different actuation dynamics and usage contexts. Finally, we present Cito, a high-fidelity proof-of-concept hardware prototype that investigates technical challenges.

INTRODUCTION

Exploring the full potential of smartwatches requires useful and usable input and output. This is challenging considering the small form factor and wearable context. Existing research has primarily focused on smartwatch input [7, 12, 14, 16, 19, 21, 29, 37, 46, 57, 65, 72] with little work on output. Smartwatch output has mainly focused on extending the display region such as projecting visual content onto the forearm [45], adding a miniature secondary display on the watch band [4], adding a second watch face [63], or converting the entire watch band into a touchscreen [38]. Haptic output has also been explored, and was found effective in many usage sce-

We propose extending smartwatch output by physically actuating a watch face in five ways: rotating on its normal axis, hingeing on side, rising vertically, translating along the forearm, and orbiting around the wristband (Figure 1). These movements can be used for a variety of new interactions. For example, when a user has dirty hands (e.g., gardening), the watch face can *translate* outside of a shirt sleeve to make it visible when a notification arrives. When a user is carrying something heavy, the watch face can *orbit* to a visible part of the watch band. When a user is talking to another person, the face can *rotate* towards the other person to provide a better viewing angle. If a user needs to receive GPS navigation instructions while they do something else on the watch, the face can physically *rotate* to indicate when to turn a corner. Finally, the watch could *rise* when the phone rings, enabling the user to decline the call eyes-free by pressing the face down like a haptic force-feedback button.

Our focus is on the Human-Computer Interaction aspect of an actuated watch, we iteratively evaluate prototypes of different fidelity, iterate and refine them for users. In our first study, we elicit user feedback from 20 participants about actuated watch movements in seven usage scenarios via conceptual videos using a passive prototype. The result confirmed the usefulness of an actuated smartwatch for addressing limitations of a fixed watch face. To further advance our understanding, we conducted another 20-participant study to investigate the social acceptability and comfort of various actuation dynamics when performed in front of different audiences. Forty actuations were presented using 3D animations. The results suggest kinds of movements that should be

Figure 1. Our self-contained projection smartwatch (A) provides rectified graphics with touch input on the skin (B). We use a slide-to-unlock mechanism to reject inadvertent touches and provide a rapid projection calibration (C) before apps can be used (D).

ABSTRACT

Compact, worn computers with projected, on-skin touch interfaces have been a long-standing yet elusive goal, largely written off as science fiction. Such devices offer the potential to mitigate the significant human input/output bottleneck inherent in worn devices with small screens. In this work, we present the first, fully-functional and self-contained projection smartwatch implementation, containing the requisite compute, power, projection and touch-sensing components to support up to 40 times more of interactive surface area – more than five times that of a typical smartwatch display. We demonstrate continuous 2D finger tracking with interactive, rectified graphics, transforming the arm into a touchscreen. We discuss our hardware and software implementation, as well as evaluation results regarding touch accuracy and projection visibility.

CHI 2018

Xiao et.al. from CMU

INTRODUCTION
Appropriating the human body as an interactive surface is attractive for many reasons. Foremost, skin provides a natural and immediate surface for dynamic, digital projection. Although it introduces some color and physical distortion, the resolution, framerate and overall quality can be high [14, 16, 30, 49]. More importantly, it offers considerable surface area for interactive tasks – many times that of e.g., a smartwatch display. With today’s smartwatches containing multi-touchscreen displays, the chief bottleneck is their small touchscreens, and the chief bottleneck to unlocking richer and more useful applications. Indeed, several widely-publicized, *conceptual* on-skin projection watches have been proposed, most notably Ciceret [6] and Ritor [37].

A second benefit is that our bodies are always with us, and are often immediately available [39, 45]. This stands in contrast to conventional mobile devices, which typically reside in pockets or bags, and must be retrieved to access even basic functionality [2, 17, 38]. This generally demands a high level of attention, both cognitively and visually, and can be socially disruptive. Further, physically retrieving a device incurs a non-trivial time cost, and can constitute a significant fraction of a simple operation’s total time [1].

Fig. 1. a) Calico system deployed on a user. b) Calico wearable on the wrist. c) Calico robot moving on the pants. Different colored tracks can be used to blend into clothing. d) Calico moving towards a turntable to switch tracks. e) Running while wearing the Calico system.

We explore Calico, a miniature relocatable wearable system with fast and precise locomotion for on-body interaction, actuation and sensing. Calico consists of a two-wheel robot and an on-cloth track mechanism or "railway" on which the robot travels. The robot is self-contained, small in size, and has additional sensor expansion options. The track system allows the robot to move along the user's body and reach any predetermined location. It also includes rotational switches to enable complex routing options when diverging tracks are presented. We report the design and implementation of Calico with a series of technical evaluations for system performance. We then present a few application scenarios, and user studies to understand the potential of Calico as a dance trainer and also explore the qualitative perception of our scenarios to inform future research in this space.

Figure 1. A duet of interaction between a handheld and a wrist worn device (a): the watch is used as a tool palette when annotating text on the phone (b); a simultaneous pinch-to-close swipe gesture on both devices mute their notifications (c); the watch's orientation indicates which hand part causes a touch, thus enabling a seamless transition between modes: for example, writing with the pad of the finger (d), scrolling with side of the finger (e), and text selection with the knuckle (f).

ABSTRACT

The emergence of smart devices (e.g., smart watches and smart eyewear) is redefining mobile interaction from the solo performance of a smart phone, to a symphony of multiple devices. In this paper, we present Duet – an interactive system that explores a design space of interactions between a smart phone and a smart watch. Based on the devices' spatial configurations, Duet coordinates their motion and touch input, and extends their visual and tactile output to one another. This transforms the watch into an active element that enhances a wide range of phone-based interactive tasks, and enables a new class of multi-device gestures and sensing techniques. A technical evaluation shows the accuracy of these gestures and sensing techniques, and a subjective study on Duet provides insights, observations, and guidance for future work.

INTRODUCTION

Interactive computing technology is becoming increasingly ubiquitous. Advances in processing, sensing, and displays have enabled devices that fit into our palms and pockets (e.g., [2, 15]), that are wrist-worn [27, 40] or head-mounted [20, 29], or that are embedded as smart clothing [28, 37]. Commercialization is rapidly catching up with the research community's vision of mobile and ubiquitous form factors: smart phones, smart watches, and smart eyewear are all available for purchase. Soon, many of us may carry not one smart device, but two, three, or even more on a daily basis.

For interaction designers, this introduces a new opportunity to leverage the availability of these devices to create new interactions beyond the usage of a single device alone. At present, the space of interaction techniques making use of this opportunity is underexplored, primarily focusing on

BeamBand: Hand Gesture Sensing with Ultrasonic Beamforming

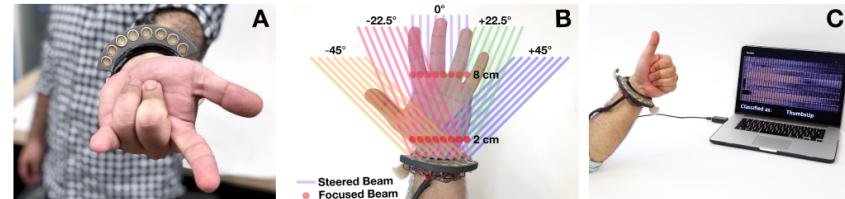

Figure 1. BeamBand is a wrist-worn sensor containing eight transducers (A) that uses beamforming to direct and focus ultrasound at areas of interest (B) in order to recognize a variety of hand gestures (C).

ABSTRACT

BeamBand is a wrist-worn system that uses ultrasonic beamforming for hand gesture sensing. Using an array of small transducers, arranged on the wrist, we can ensemble acoustic wavefronts to project acoustic energy at specified angles and focal lengths. This allows us to interrogate the surface geometry of the hand with inaudible sound in a raster-scan-like manner, from multiple viewpoints. We use the resulting, characteristic reflections to recognize hand pose at 8 FPS. In our user study, we found that BeamBand supports a six-class hand gesture set at 94.6% accuracy. Even across sessions, when the sensor is removed and re worn later, accuracy remains high: 89.4%. We describe our software and hardware, and future avenues for integration into devices such as smartwatches and VR controllers.

1 INTRODUCTION

Robust hand gesture detection holds the promise to enrich user interfaces and improve immersiveness, whether it be smartwatches to AR/VR systems. Unfortunately, identifying hand gestures without instrumenting the hand (e.g., gloves, controllers) has proven to be challenging, which motivates the need to identify new methods. Prior research includes leveraging electromyography [38][39], bio-acoustics [23][15], electrical impedance tomography [50][51], contour sensing [7], and worn cameras [20]. While each approach has its strengths and drawbacks, a common weakness is robust accuracy across users and worn sessions.

In this paper, we present our work on BeamBand, a new approach for worn hand gesture sensing, which leverages acoustic beamforming. We use small in-air ultrasonic transducers arranged along the contour of the wrist (Figure 1A), which offers a stable vantage point from which to capture hand pose. Using active beamforming, we steer and focus ultrasound towards areas of interest on the hand (Figure 1B). We also multiplex our transducers, capturing beamformed reflections from slightly different viewpoints (Figure 1B), offering rich signals for machine-learning-driven hand gesture recognition (Figure 1C).

To assess BeamBand's recognition performance, we conducted a ten-participant study, adopting two gesture sets from the literature in order to enable direct comparison (i.e., rather than developing a custom set). The first set contained seven hand poses, while the second set has six gestures along three axes of rotation. On these two gesture sets, BeamBand demonstrates accuracies of 92.5% and 94.6%
